OVERVIEW

The AMIGA computer is a high-performance system with advanced graphics and audio features. The Functional Block Diagram on page 4 illustrates the relationship of the various circuits on the Main Logic board and Piggyback. The principle hardware features consist of the 68000 microprocessor which runs at 7.2 MHz, 256K bytes of RAM (user expandable to 512K, configurable to 8M), 2 parallel I/O chips and 3 custom VLSI chips that provide the unique capabilities for animation, graphics and sound.

68000 MICROPROCESSOR

The 68000 is the CPU of the system. All other resources are under software control via control data issued from it. All 3 custom chips have control registers that are written by the 68000.

The 68000 communicates with the rest of the computer via its address bus, data bus and control lines. Notice that in the block diagram the 3 custom chips do not reside directly on the 68000 buses. When the 68000 starts a bus cycle that is intended for the custom chips or the display RAM, the bus control logic detects whether or not the display RAM buses are available. The bus control logic will not assert the acknowledge signal (/DTACK) back to the 68000 until the display RAM buses are available. Once the 68000 receives /DTACK it completes the bus cycle. Connecting the display RAM buses to the 68000 buses is discussed further in the section on bus control and multiplexers. Because the display RAM is capable of approximately twice the bandwidth of the 68000, the 68000 is usually not delayed by waiting for the display buses to become available.

The 68000 can fetch instructions from:

- Boot ROM
- Processor RAM
- Display RAM

The 68000 can read and write data directly to:

- Boot ROM (Read Only)
- Processor RAM (After boot this is Read Only)
- Display RAM
- Parallel I/O Chips
- 3 Custom I.C.s

The 68000 transmits data and control to and from the peripherals via the parallel I/O and the 3 custom chips.

7M is the processor clock to the 68000. C1-C4 and /DAC are used to clock the custom chips and for determining the timing of signals to the memory arrays.

BOOT ROM

The boot ROM is comprised of 2 standard 32K byte ROMS configured in parallel to form a 32K word that includes the routines for bringing in additional code from the floppy disk.

PROCESSOR RAM

This 256K byte RAM is intended to hold kernal and DOS routines. It has associated logic which allows it to be write protected once it has been loaded. This allows it to function as ROM once the boot load has been completed. Except during the boot sequence, "writes" to this RAM are prevented.

This RAM and its associated buffers and logic are resident on the piggyback board (daughter card), which is attached to the main board.

PARALLEL I/O

The 2 multi-purpose 8520 I/O chips provide the following:

- I/O to and from the parallel port connector
- Control lines to and from the joystick/mouse ports
- A control line to the front panel LED
- Internal control lines
- Keyboard control lines, clock and data
- Serial port control lines
- Floppy disk interface control lines
- Internal timers

These 2 chips reside on the 68000 buses and are read and written by the 68000.

CLOCKS GENERATOR

The entire computer board is run synchronous to the 3.579545 MHz color clock. This is accomplished by generating a number of submultiple frequencies from the master 28.31818 MHz crystal oscillator. In order to reduce high frequency radiation, all clock generation is done in the small metal RF can on the main logic board. The following are the primary clocks:

| | |
|------|--------------------------------|
| C1 | 3.579545 MHz color clock |
| C2 | C1 shifted 45 degrees later |
| C3 | C2 shifted 45 degrees later |
| C4 | C3 shifted 45 degrees later |
| 7M | C1 XORed with C3 = 7.15909 MHz |
| /DAC | 7M shifted 90 degrees later |

THE 3 CUSTOM CHIPS

The 3 custom chips provide very fast manipulation of graphics and audio data in the display RAM. All of the major functions in the chips are DMA driven; that is, streams of data are moved between the custom chips and display RAM under DMA control. These streams of data are acted upon by the custom chips. Agnus, custom chip #1, contains 25 dedicated purpose DMA counters.

The 3 chips have control registers which are usually loaded by the 68000. However, Agnus also has the capability of loading control registers in the other 2 custom chips. When Agnus performs a bus cycle, it outputs a code on the Register Address Bus telling the other 2 chips the nature of the bus cycle. This is necessary because many of the bus cycles provide data to or from the other 2 chips, thus they must cooperate appropriately.

In addition to manipulating data in the display RAM, the custom chips output streams of data to the video output circuits, audio output circuits and move data to and from the floppy disks and serial port.

Note that the display RAM buses can be completely isolated from the 68000 buses by the multiplexers and drivers. Thus, Agnus can be performing a bus cycle on the display buses simultaneously with the 68000 performing a bus cycle on its buses. This parallelism increases throughput.

BUS CONTROL, ADDRESS/DATA MUX, ADDRESS DRIVER

The bus control logic resides primarily in 4 PALs on the piggyback board. They provide the logic for connecting the 68000 buses to the display RAM buses when the 68000 is attempting to access the display RAM or the custom chips. To do this, the bus control logic must perform 3 major functions:

- Synchronize the 68000 to the current phase of C1
- Arbitrate between the 68000 and Agnus for the display buses
- Turn on the muxes and bus drivers appropriate to the current cycle

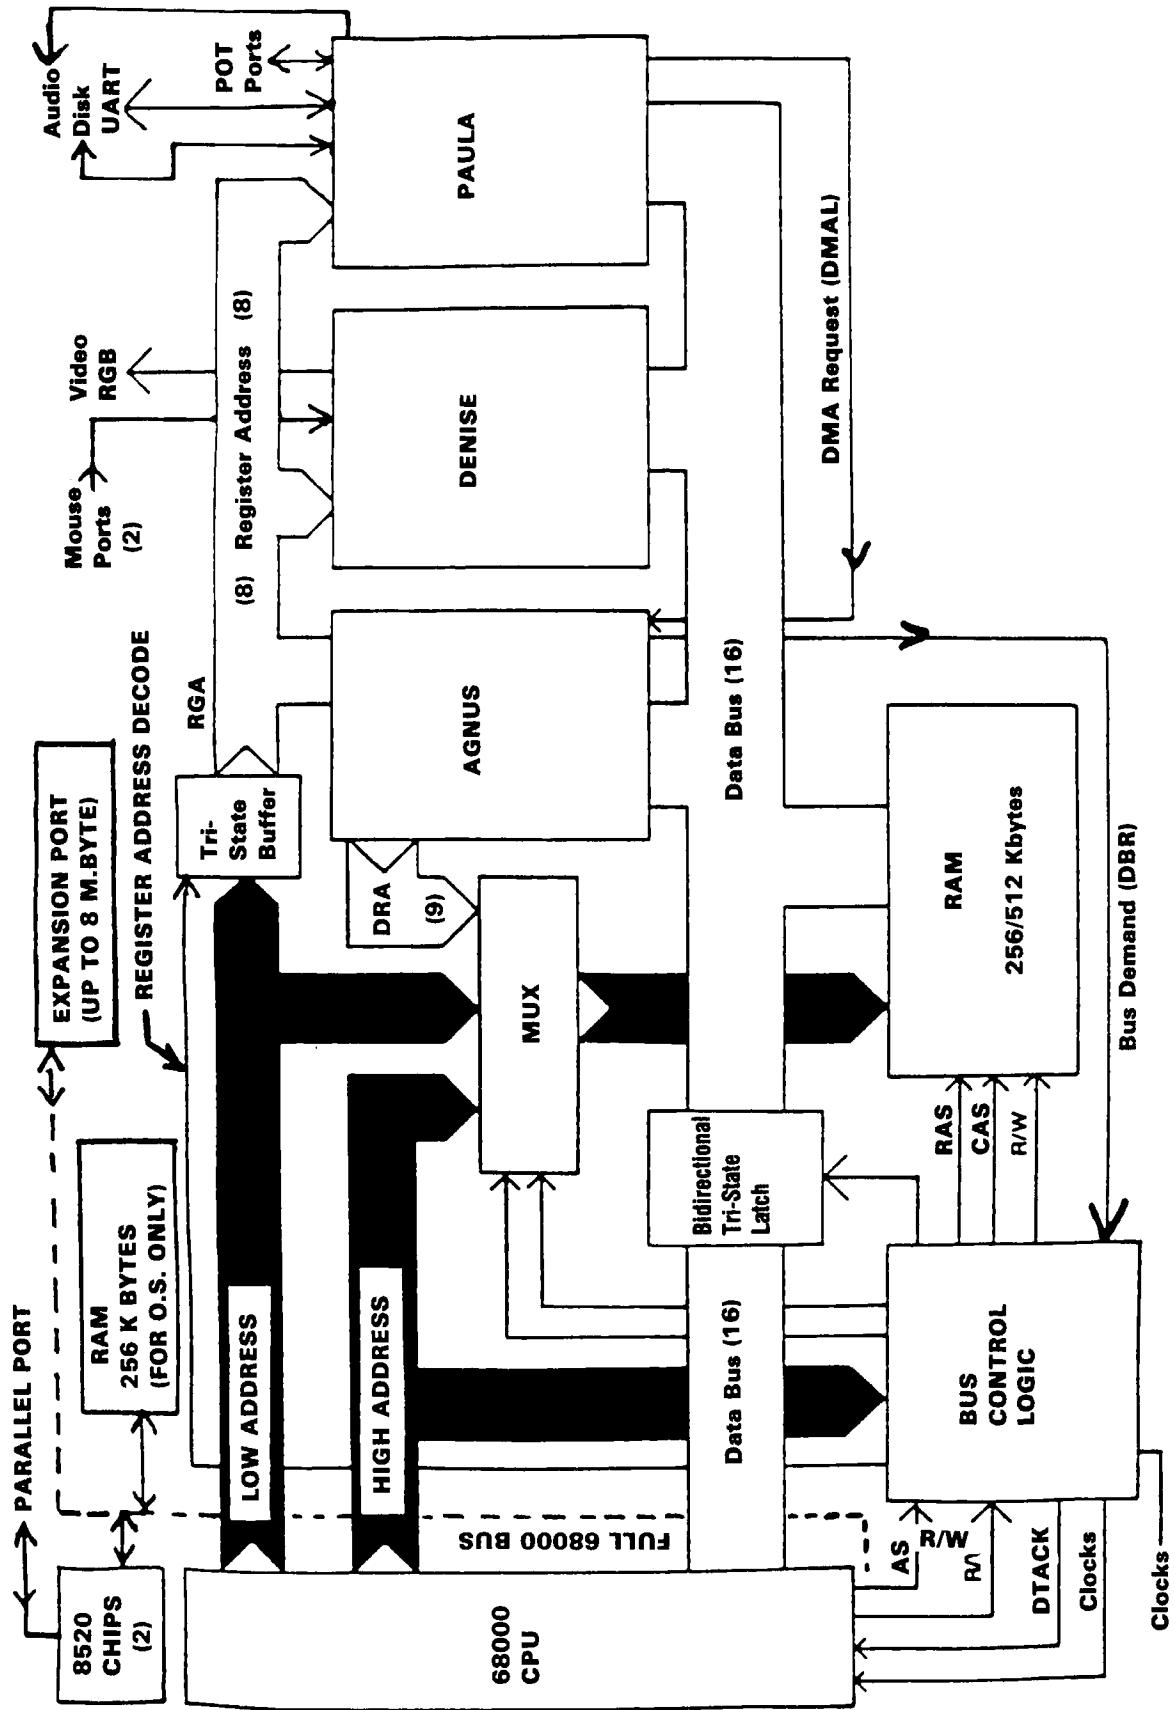

Synchronizing the 68000 to C1 is straightforward, since the 68000 is clocked by 7M which is twice the frequency and synchronous to C1. If the 68000 starts a bus cycle in the wrong phase of C1, the bus control logic merely delays /DTACK long enough so that the 68000 will complete the bus cycle in the desired phase relationship to C1. This phase relationship is necessary because the custom chips and the display RAM are clocked by C1.

Arbitration is very simple. Agnus tells the bus control prior to taking the display RAM buses by asserting an input to the PALs called /DBR. Whenever Agnus has the display buses and the 68000 wants them, the 68000 is held off by not giving it /DTACK. In this state the 68000 has no affect on the display buses until the bus controller enables the bus drivers and multiplexers, after Agnus has given up the display buses.

DISPLAY RAM

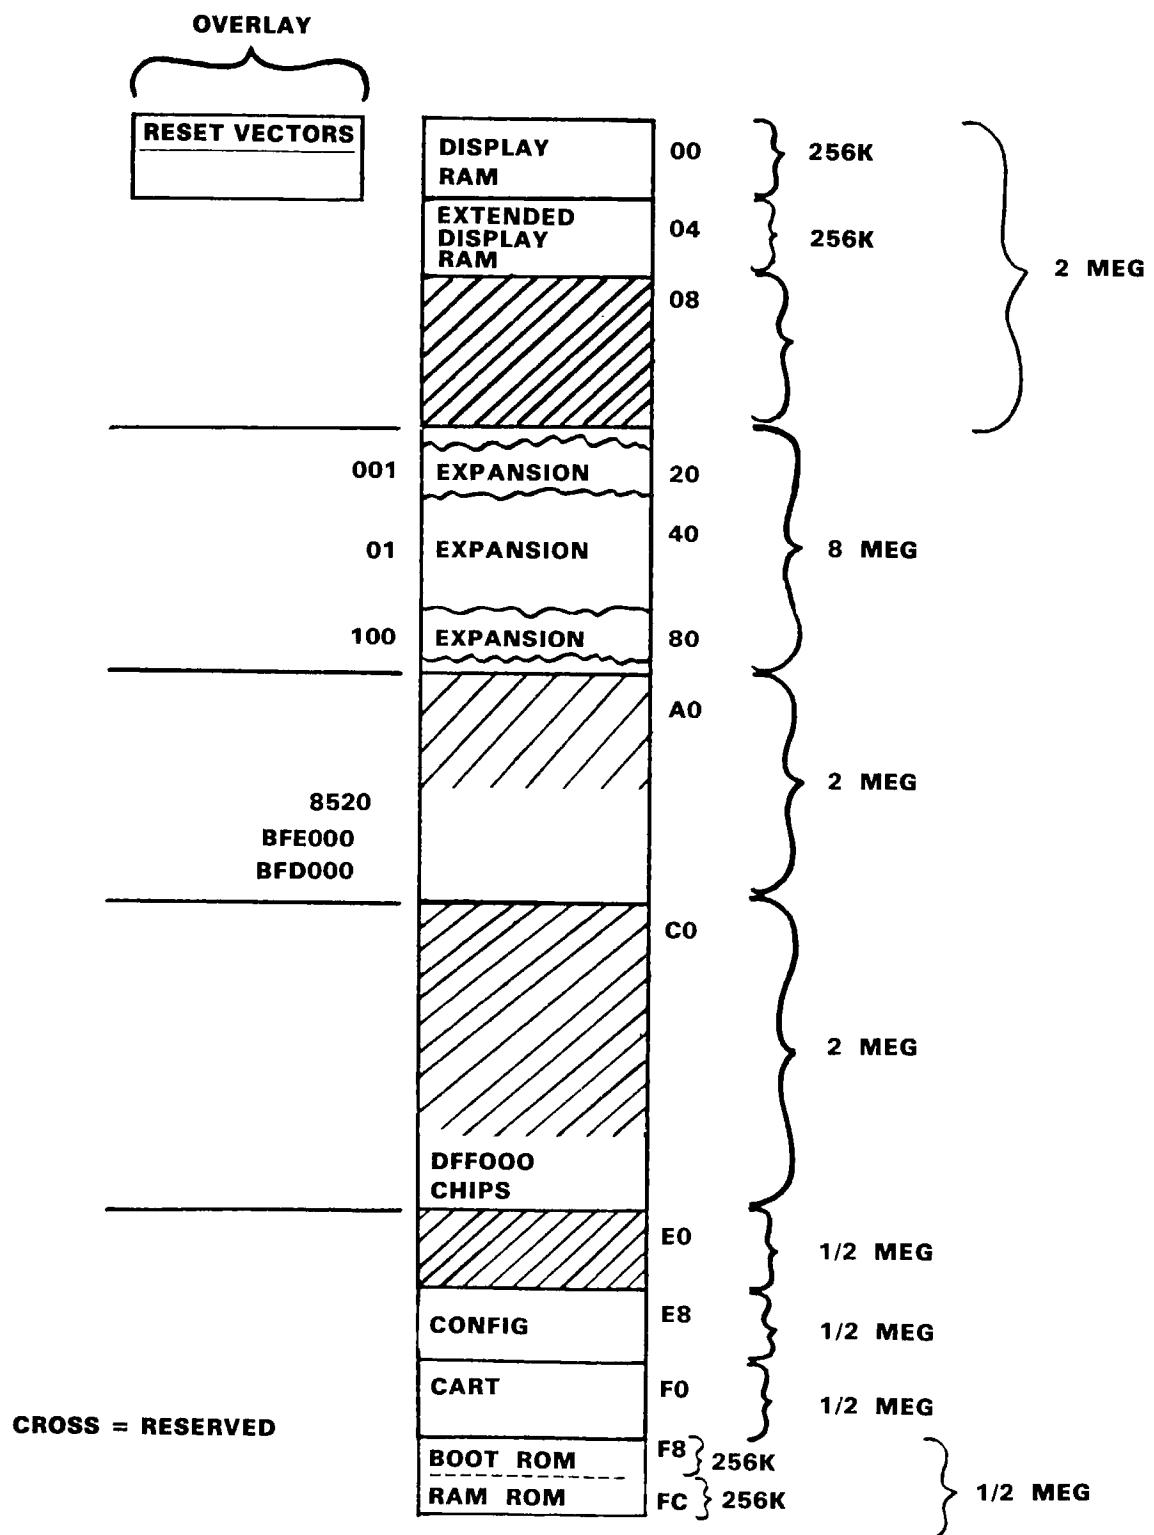

The display RAM is an ordinary 256K byte read/write memory that resides on the RAM address and RAM data buses. It is expandable to 512K bytes by the addition of the RAM expansion module. It is implemented using standard dynamic RAMs, refreshed by Agnus.

The display RAM is really used for much more than just holding graphics data. It also stores code and data for the 68000.

CUSTOM ANIMATION CHIP

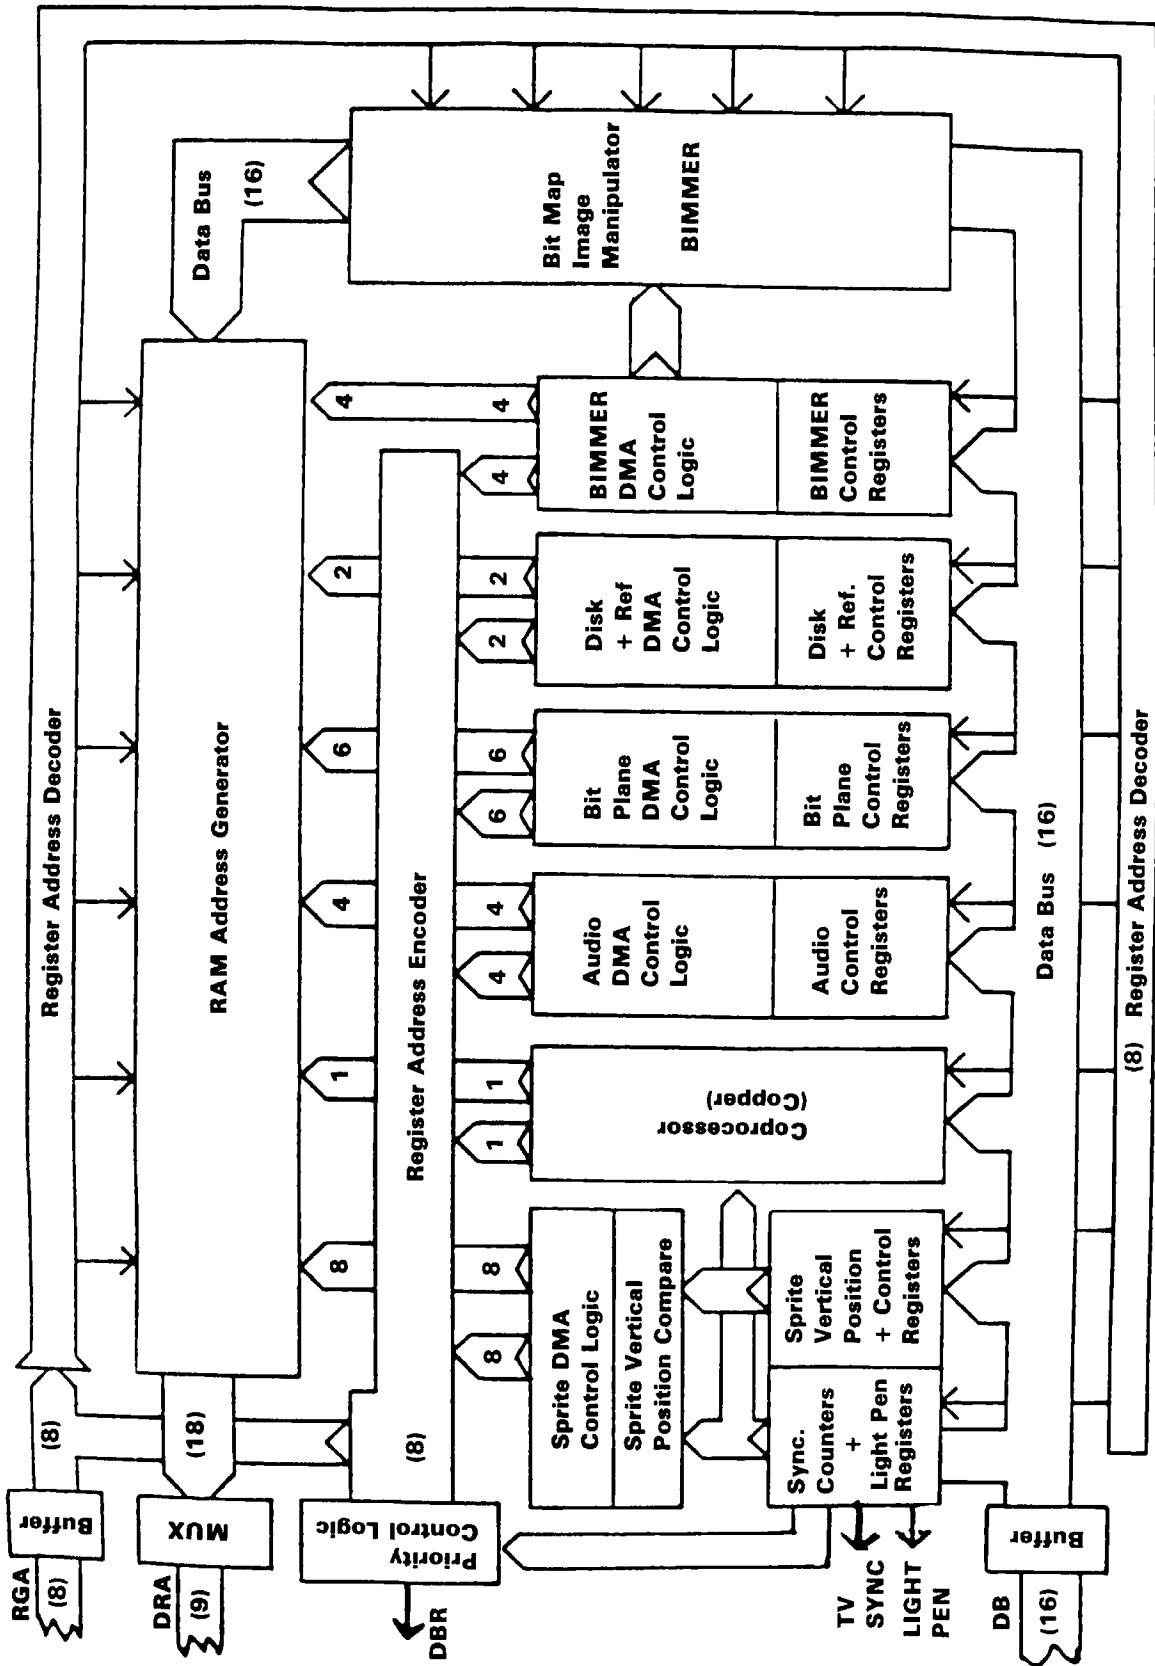

— Agnus —

FEATURES:

- Bit Blitter — Uses Hardware to Move Display Data — Allows High Speed Animation — Frees the CPU for other Concurrent Tasks
- Display Synchronized Coprocessor
- Controls 25 DMA Channels — Allows the Disk and Sound to Operate with Minimal CPU intervention

AGNUS BLOCK DIAGRAM

CUSTOM GRAPHICS CHIP

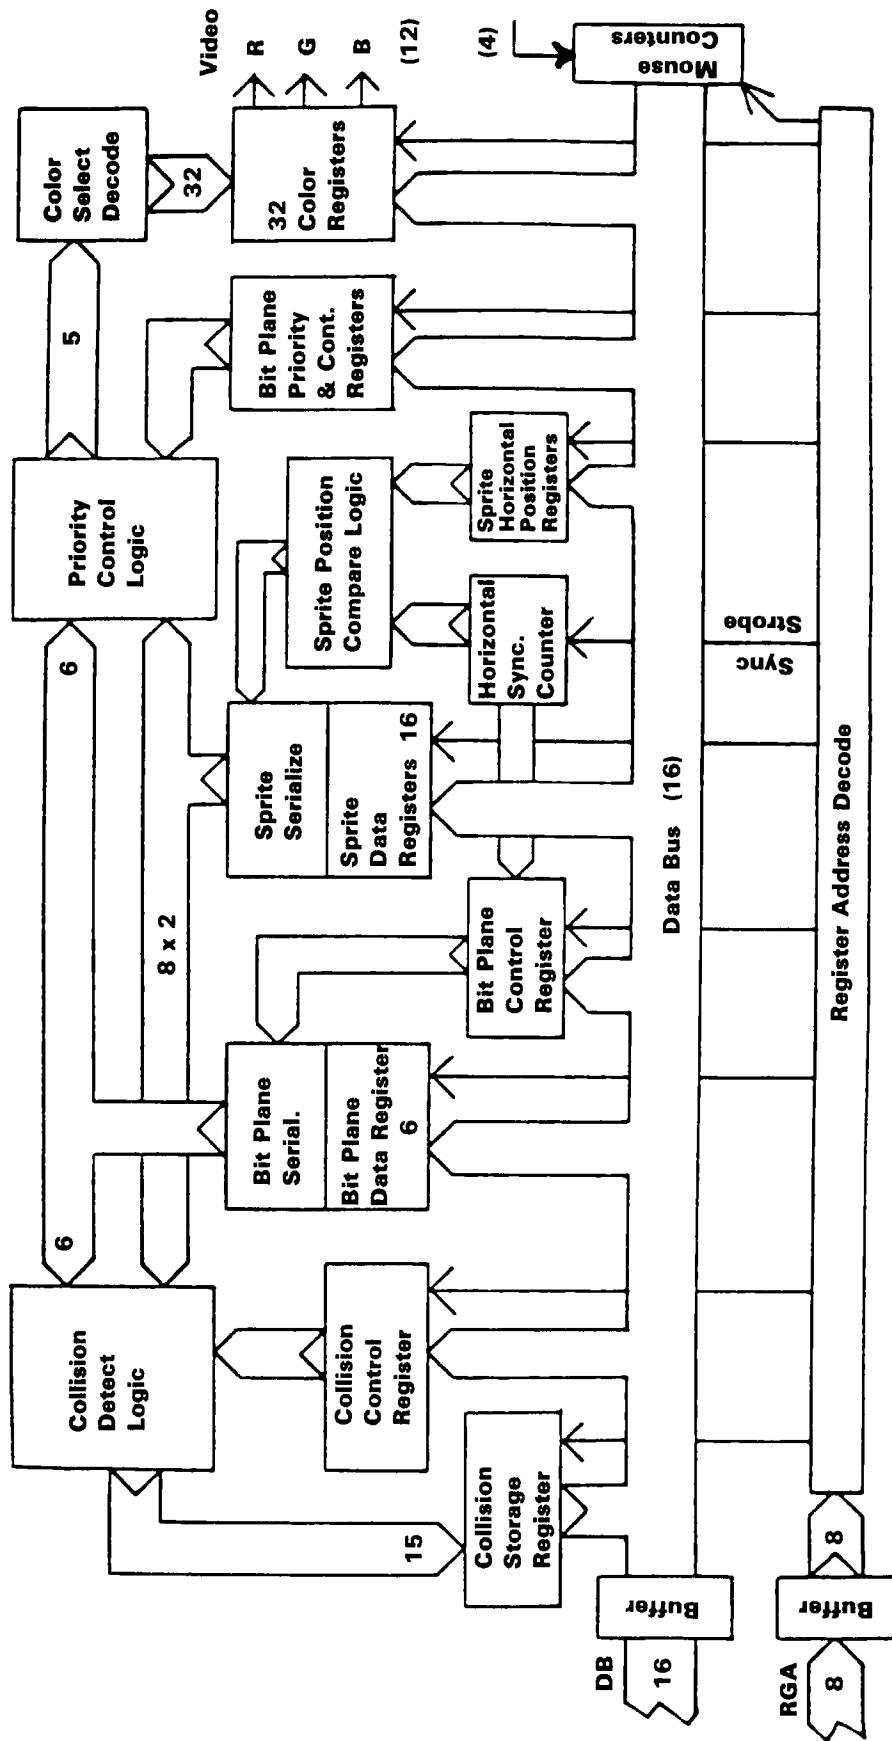

— Denise —

FEATURES:

- Many Different Resolutions 320 X 200 up to 640 X 400
- 4096 Colors on a TV or RGB Monitor
- Eight Re-usable Sprite Controllers
- 60 or 80 Column Text
- Same Software for All TVs and Monitors

CUSTOM SOUND/PERIPHERALS CHIP

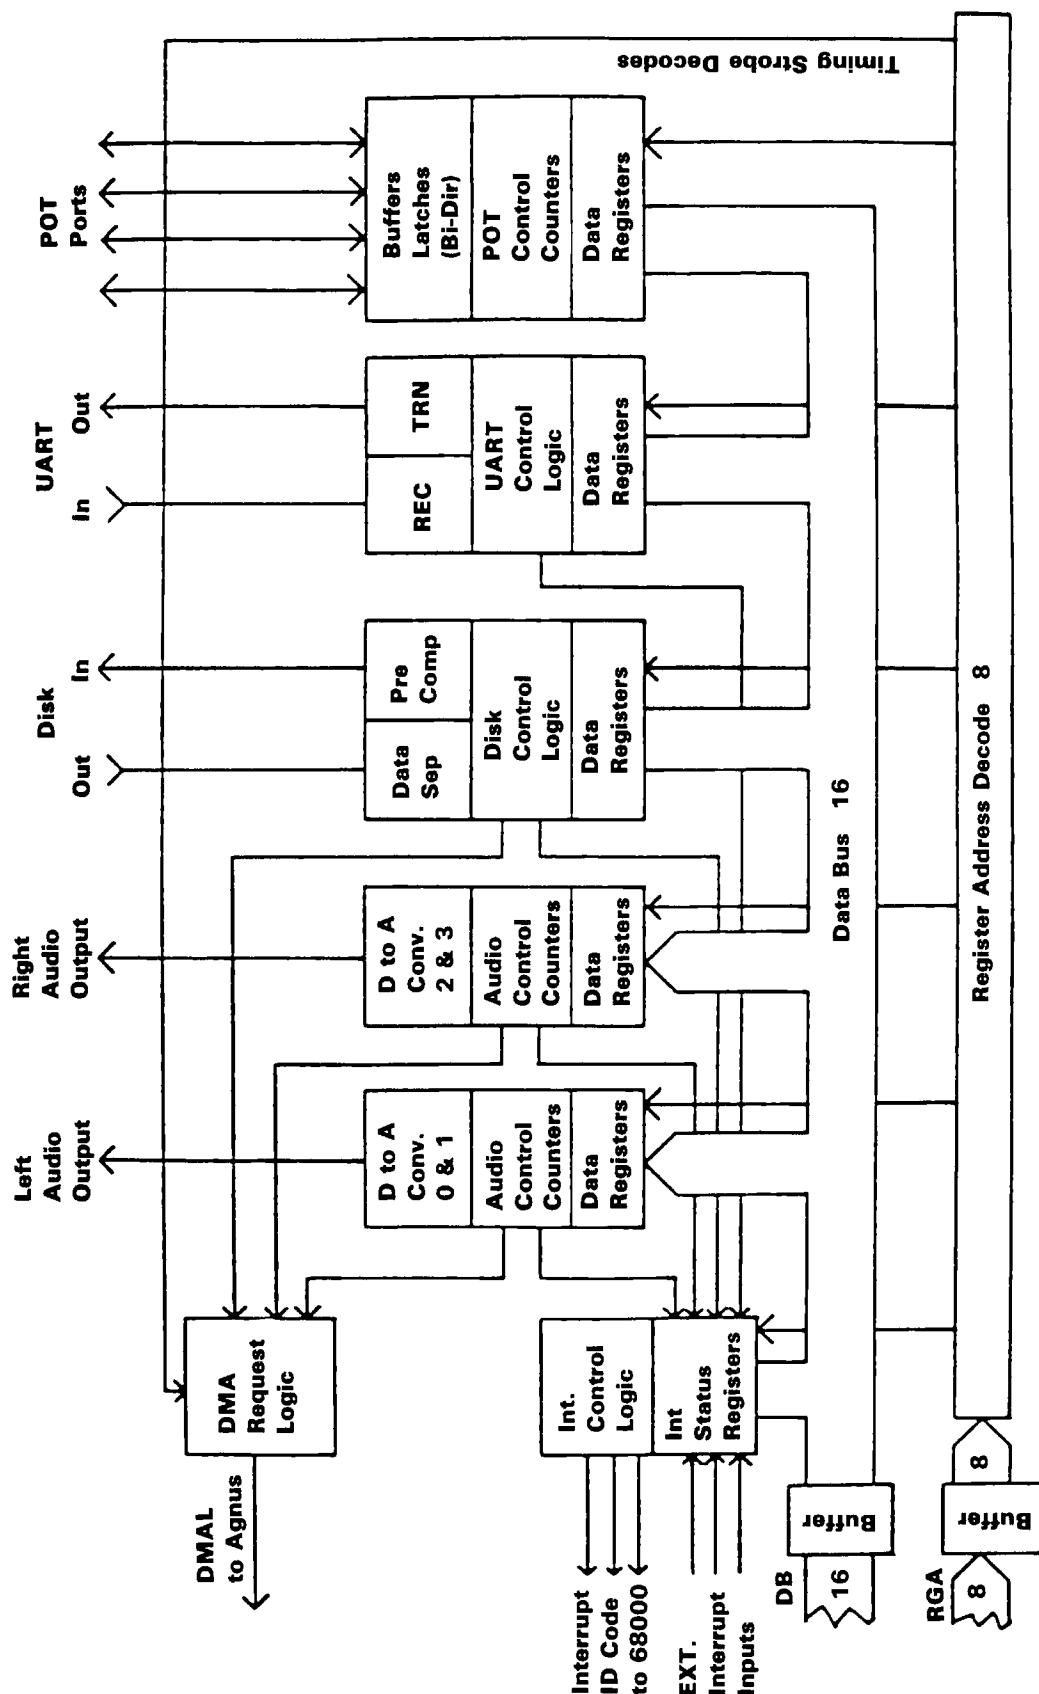

— Paula —

FEATURES:

- Four Voices of Sound Output configured as Two Stereo Channels
- Nine Octaves
- Complex Waveforms
- Uses both Amplitude and Frequency Modulation
- I/O Controls for Disk Data and Controller Ports
- Microdisk Controller
- Interrupt Control System

AMIGA MAIN LOGIC PCB ASSY #327137**

CBM APPROVED VENDORS FOR GENERIC PARTS

Component parts are stocked by Commodore if they are custom, proprietary or difficult to obtain in the field. Those common components that are available from many sources are considered GENERIC and are best obtained from your local parts distributor. Often critical parameters may vary between manufacturers and will affect the performance of a product. It is strongly RECOMMENDED that you use only parts from vendors that have been qualified and APPROVED by Commodore for use in our products. If you have a board with ORIGINAL parts and the vendor is not listed as approved, you may assume that the vendor was approved after this printing and also may be used as a replacement part.
